

Daniel White

We all know one metric of the quality of a product is the number of bugs found in it. The more bugs found, the better the product is. This is a common misconception. In fact, the more bugs found, the worse the product is. The reason for this is that bugs are a sign of poor quality control. If a product has many bugs, it means that the developers did not test the product thoroughly enough. This is a sign of carelessness and a lack of attention to detail. The result is a product that is unreliable and prone to failure. In contrast, a product with few bugs is a sign of high quality control. The developers have taken the time to test the product thoroughly and have found and fixed any bugs. This is a sign of care and attention to detail. The result is a product that is reliable and of high quality.
